

Primes matrix: Approximation 2

Since I wasn't happy about the final sum in my last post Primes matrix: Approximation, I think about an alternative way.

We had

$$x_{(a,\dots,b),kj} = \lim_{m \rightarrow \infty} \left(\prod_{i=a}^b \exp \left(I2\pi \frac{k-x_i}{2x_i+1} \epsilon(m) \right) \right) \delta_{kj} = \lim_{m \rightarrow \infty} \exp \left(\sum_{i=a}^b I2\pi \frac{k-x_i}{2x_i+1} \epsilon(m) \right) \delta_{kj}$$

in which we made the product over all exp-functions for each x_i . Now, instead we will do the product over the arguments of the exp-functions

$$x_{(a,\dots,b),kj} = \lim_{m \rightarrow \infty} \exp \left(\prod_{i=a}^b I2\pi \frac{k-x_i}{2x_i+1} \epsilon(m) \right) \delta_{kj}$$

Let's look at the qualities of this product

$$\prod_{i=a}^b \frac{k-x_i}{2x_i+1}$$

and under which conditions we receive integers. From my work <https://github.com/Samdneyn/primescalc> we already know that we get troubles if at least one of the $2x_i+1$ is a divisible number. Hence, we always assume that all our numbers $2x_i+1$ are primes.

We receive integer values in the following cases

- **Case 1:** For all k -values which are also solutions for every single exp-equation.
- **Case 2:** For all k -values which is a solution for at least one single exp-equation and also leads to the trivial solution with $x_{(1),j} = N(2x_{(2),i}+1)$, $N \in \mathbb{N}$.

For the second case, we take the example of two equations with $x_1 = 2$ and $x_2 = 3$

$$\frac{k-x_1}{2x_1+1} \frac{k-x_2}{2x_2+1} = \frac{(k-2)(k-3)}{5 \cdot 7}$$

Here we receive one solution for $k = 37$, $\frac{35 \cdot 34}{35} = 34$, which is also a solution for $\frac{37-2}{5} = 7$ and another solution for $k = 38$, $\frac{36 \cdot 35}{35} = 36$ which is also a solution

for $\frac{38-3}{7} = 5$. We see that k leads to the trivial case in which x_j of one single exp-equation is equal to the prime value of an other single exp-equation or the product of primes of several single exp-equations.
